The</div>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | <div>10</div> <div>AST is an array that can contain strings and objects. Any strings represent plain text content to be written to the output. Any objects represent HTML tags. Tag objects generally look something like this:</div> <div><pre>{   tag: 'div',   attrs: {     class: 'foo'   }, }</pre></div>                                                                                                                                                                                                                                                      | <div>11</div> <div><pre>    content: ['hello world!']   } }</pre></div> <div>Tag objects can contain three keys. The tag key takes the name of the tag as the value. This can include custom tags. The optional attrs key takes an object with key/value pairs representing the attributes of the html tag. A boolean attribute has an empty string as its value. Finally, the optional content key takes an array as its value, which is a PostHTML AST. In this manner, the AST is a tree that should be walked recursively.</div> | <div>12</div> <div>Options</div> <div>directives</div> <div>Type: Array Default: [{name: '!doctype', start: '&lt;', end: '&gt;'}] Description: Adds processing of custom directives. Note: The property name in custom directives can be String or RegExp type</div>                                                                                                                            |
| <div>16</div> <div>lowerCaseAttributeNames</div> <div>Type: Boolean Default: false Description: If set to true, CDATA sections will be recognized as text.</div> <div>recognizeSelfClosing</div> <div>Type: Boolean Default: false Description: If set to true, self-closing tags will trigger the oncloseTag event even if xmlMode is not set to true.
